Infection Control for the Surgeon

Gonzalo Bearman, MD, MPH
Assistant Professor of Internal Medicine & Epidemiology
Associate Hospital Epidemiologist
VCU Medical Center
August 23rd, 2006
Nosocomial Infections

• 5-10% of patients admitted to acute care hospitals acquire infections
  – 2 million patients/year
  – ¼ of nosocomial infections occur in ICUs
  – 90,000 deaths/year
  – Attributable annual cost: $4.5 – $5.7 billion
  • Cost is largely borne by the healthcare facility not 3rd party payors

Nosocomial Infections

- 70% are due to antibiotic-resistant organisms
- Invasive devices are more important than underlying diseases in determining susceptibility to nosocomial infection

# Attributable Costs of Nosocomial Infections

<table>
<thead>
<tr>

Shifting Vantage Points on Nosocomial Infections

Many infections are inevitable, although some can be prevented

Each infection is potentially preventable unless proven otherwise

Major Sites of Nosocomial Infections

- Urinary tract infection
- Bloodstream infection
- Pneumonia (ventilator-associated)
- Surgical site infection
Nosocomial Urinary Tract Infections
Nosocomial Urinary Tract Infections

- Most common hospital-acquired infection (40% of all nosocomial infections)
  - 1 million cases of nosocomial UTI per year in the US
- Of nosocomial infections, lowest mortality & cost
- >80% associated with urinary catheter
Nosocomial Urinary Tract Infections

- 25% of hospitalized patients will have a urinary catheter for part of their stay
- 20-25 million urinary catheters sold per year in the US
- Incidence of nosocomial UTI is ~5% per catheterized day
- Virtually all patients develop bacteriuria by 30 days of catheterization
- Of patients who develop bacteriuria, 3% will develop bacteremia

Risk Factors for Nosocomial UTIs

- Female gender
- Diabetes mellitus
- Renal insufficiency
- Duration of catheterization
- Insertion of catheter late in hospitalization
- Presence of ureteral stent
- Using catheter to measure urine output
- Disconnection of catheter from drainage tube
- Retrograde flow of urine from drainage bag
Prevention of Nosocomial UTIs

- Avoid catheter when possible & discontinue ASAP
- Aseptic insertion by trained HCWs
- Maintain closed system of drainage
- Ensure dependent drainage
- Minimize manipulation of the system
- Condom or suprapubic catheter
- Silver coated catheters
Nosocomial Bloodstream Infections
Nosocomial Bloodstream Infections

- 12-25% attributable mortality
- Risk for bloodstream infection:

<table>
<thead>
<tr>
<th>Catheter Type</th>
<th>BSI per 1,000 catheter/days</th>
</tr>
</thead>
<tbody>
<tr>
<td>Subclavian or internal jugular CVC</td>
<td>5-7</td>
</tr>
<tr>
<td>PICC</td>
<td>0.2 - 2.2</td>
</tr>
</tbody>
</table>
Risk Factors for Nosocomial BSIs

- Heavy skin colonization at the insertion site
- Internal jugular or femoral vein sites
- Duration of placement
- Contamination of the catheter hub
The importance of process of care measures in the reduction of nosocomial bloodstream infections
The CVC is the greatest risk factor for Nosocomial BSI

As the host cannot be altered, preventive measures are focused on risk factor modification of catheter use, duration, placement and manipulation.
Prevention of Nosocomial BSIs

- Limit duration of use of intravascular catheters
  - No advantage to changing catheters routinely
- Maximal barrier precautions for insertion
  - Sterile gloves, gown, mask, cap, full-size drape
  - Moderately strong supporting evidence
- Chlorhexidine prep for catheter insertion
  - Significantly decreases catheter colonization
  - Disadvantages: possibility of skin sensitivity to chlorhexidine
Eliminating catheter-related bloodstream infections in the intensive care unit

– Purpose:
  – To determine whether a multifaceted systems intervention would eliminate catheter-related bloodstream infections (CR-BSIs)

– Method:
  – Prospective cohort study in a surgical intensive care unit (ICU) with a concurrent control ICU.

– Patients:
  – All patients with a central venous catheter in the ICU

Eliminating catheter-related bloodstream infections in the intensive care unit

<table>
<thead>
<tr>
<th>Interventions</th>
<th>Example</th>

<td>SICU attending physician notified</td>
</tr>
</tbody>
</table>

Eliminating catheter-related bloodstream infections in the intensive care unit

• Results:
  – During the first month nursing completed the checklist for 38 procedures:
    • Eight (24%) for new central venous access,
    • 30 (79%) for catheter exchanges over a wire,
    • Three (8%) were emergent.
  – Nursing intervention was required in 32% (12/38) of central venous catheter insertions

### Eliminating catheter-related bloodstream infections in the intensive care unit

<table>

</tbody>
</table>

Multifaceted, comprehensive program requiring CVC insertion education, with safety checks for proper hand hygiene, aseptic insertion procedure and operator responsibility can result in reduction of nosocomial BSI in an ICU setting.

Nosocomial Pneumonia
Nosocomial Pneumonia

- Cumulative incidence = 1-3% per day of intubation
- Early onset (first 3-4 days of mechanical ventilation)
  - Antibiotic sensitive, community organisms (S. pneumoniae, H. influenzae, S. aureus)
- Late onset
  - Antibiotic resistant, nosocomial organisms (MRSA, Ps. aeruginosa, Acinetobacter spp, Enterobacter spp)
Risk Factors for VAP

- Duration of mechanical ventilation
- Chronic lung disease
- Severity of illness
- Age
- Head trauma
- Elevated gastric pH
- Aspiration of gastric contents
- Reintubation
- Upper abdominal or thoracic surgery
- Supine head position
- NG tube
Prevention of VAP

- Semirecumbent position of ventilated patients (head of bed at 30-45°)
- Continuous oscillation: needs more study
- Continuous aspiration of subglottic secretions
  - Uses ETT with a dorsal lumen that opens into the subglottic region, allowing aspiration of pooled secretions with potential pathogens
  - Delays onset of VAP, conflicting evidence on incidence of VAP, no effect on mortality
Prevention of VAP

• Selective GI tract decontamination
  – Many studies
  – Complicated literature
    • Some studies used topical as well as IV antibiotics
  – Major concern: development of antibiotic resistance

• Sucralfate
  – Allows prophylaxis of stress ulcers without raising gastric pH (↑ pH leads to increased gastric colonization)
  – Mixed results in the literature
  – Disadvantages: requires NG tube, provides inferior prophylaxis for GI bleeding
Surgical Site Infections
Epidemiology of SSI in the US

- 30 million surgical procedures performed annually
- SSIs occur in 2-5% of clean, extra-abdominal procedures & up to 20% of patients undergoing intra-abdominal procedures
- CDC estimates that 500,000 SSIs occur annually
- Direct + indirect costs = $1-$10 billion
- 47-84% of SSIs occur after discharge
Sources of SSIs

• Endogenous: patient’s skin or mucosal flora
  – Increased risk with devitalized tissue, fluid collection, edema, larger inocula

• Exogenous
  – Includes OR environment/instruments, OR air, personnel

• Hematogenous/lymphatic: seeding of surgical site from a distant focus of infection
  – May occur days to weeks following the procedure

• **Most infections occur due to organisms implanted during the procedure**
## Surgical Site Infections

### Pathogens

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Up to 20% of skin-associated bacteria in skin appendages (hair follicles, sebaceous glands) & are not eliminated by topical antisepsis. Transection of these skin structures by surgical incision may carry the patient's resident bacteria deep into the wound and set the stage for subsequent infection.
Definition of SSI

## CDC Criteria for SSI

</tbody>
</table>
Timing of SSI Diagnosis

Risk Factors for SSI

- Age (extremes)
- Sex
  - ♀ post cardiac surgery
- Underlying disease
  - obesity (fat layer < 3 cm 6.2%; >3.5 cm 20%)
  - malnutrition
  - malignancy
  - remote infection
Risk Factors for SSI

• Duration of pre-op hospitalization
  * increase in endogenous reservoir
• Pre-op hair removal
  * esp if time before surgery > 12 hours
  * shaving>>clipping>depilatories
• Duration of operation
  * increased bacterial contamination
  * tissue damage
  * suppression of host defenses
  * personnel fatigue
Prevention of SSI
Prevention of SSI

- Limit pre-op hospitalization
- Stabilize underlying diseases
- Avoid hair removal by shaving
  - Clipping of skin is preferred
- Skin decolonization of both patient and surgeon
  - Chlorhexidine
  - Intranasal mupirocin for *S. aureus* carriers
- Impermeable drapes
  - Maximum sterile barrier precautions
- Perioperative antibiotic prophylaxis
- Tight control of perioperative glucose
Consumer Advocacy Impacting Physician Practice - affect on SSI surveillance and process of care

• Direct education of the public
• Working with state legislatures to mandate public reporting of healthcare quality issues
• Pay for performance (P4P)
SCIP

- A national partnership of organizations to improve the safety of surgical care by reducing post-operative complications through a national campaign
- Goal: reduce the incidence of surgical complications by 25 percent by the year 2010
- Initiated in 2003 by the Centers for Medicare & Medicaid Services (CMS) & the Centers for Disease Control & Prevention (CDC)
  - Steering committee of 10 national organizations
  - More than 20 additional organizations provide technical expertise
SCIP Philosophy

- Surgeons, anesthesiologists, perioperative nurses, pharmacists, infection control professionals, & hospital executives work together to intensify their commitment to improving surgical care
SCIP Steering Committee Organizations

- Agency for Healthcare Research and Quality
- American College of Surgeons
- American Hospital Association
- American Society of Anesthesiologists
- Association of perioperative Registered Nurses
- Centers for Disease Control and Prevention
- Centers for Medicare & Medicaid Services
- Department of Veterans Affairs
- Institute for Healthcare Improvement
- Joint Commission on Accreditation of Healthcare Organizations
Monetary incentives for promoting quality and compliance with SSI risk reduction guidelines:

March 12, 2005

In recent years, the healthcare industry has placed a stronger emphasis on reducing medical errors, monitoring everything from how long doctors sleep to whether or not their handwriting is legible. Now one organization is not only recognizing the hospitals that follow patient safety and clinical guidelines, but rewarding them for doing so. **Anthem Blue Cross and Blue Shield recently gave a total of $6 million to 16 Virginia hospitals as part of the company's new Quality-In-Sights Hospital Incentive Program (Q-HIP).**

Perioperative Antibiotics
Antibiotic Prophylaxis for Surgery

• Goal: reduce intraoperative microbial contamination to a level that will not overwhelm host defenses & result in infection

• Characteristics of good prophylactic antimicrobials:
  – Safe
  – Inexpensive
  – Bactericidal
  – Spectrum of activity covers the most likely contaminants for the operation

• A bactericidal concentration should be present in serum & tissues at time of incision

• Therapeutic concentrations should be maintained until, at most, a few hours after the incision is closed

Meta-analyses:
Antibiotic Prophylaxis vs Placebo

- OR 0.35; TAH; 17 trials
- OR 0.35; TAH; 25 trials
- OR 0.30; biliary surgery; 42 trials
- OR 0.20; CT surgery; 28 trials

Indications for Antibiotic Prophylaxis

- Clean-contaminated procedures
- Clean procedures that require placement of prosthetic material
- Clean procedures in which infection would be catastrophic
- Contaminated procedures
Rates of SSI based on Timing of Antibiotic Administration

- Prospective study evaluating timing of antibiotic prophylaxis and incidence of surgical site infection
- Evaluated 2,847 patients undergoing clean or clean—contaminated procedures in a 540 bed teaching hospital

Rates of SSI based on Timing of Antibiotic Administration

</tbody>
</table>
Process Indicators:

Timing of First Antibiotic Dose

Infusion should begin within 60 minutes of the incision

• Little controversy regarding this indicator

Process Indicators:
Duration of Antimicrobial Prophylaxis

Prophylactic antimicrobials should be discontinued within 24 hrs after the end of surgery

• Areas of controversy:
  – ASHP recommends continuing prophylaxis for CT surgery procedures for up to 72 hrs after the operation; Society of Thoracic Surgeons recommends 48 hrs

Proper Hair Removal
Preoperative Hair Removal

**Category I A**: Strongly recommended for implementation; supported by well designed, experimental, clinical or epidemiologic studies.

Not removing hair from the surgical site unless necessary to facilitate surgery.

If hair is to be removed, then this should be done immediately before surgery and preferably with **electric scissors** and not by shaving.

*CDC Hospital Infection Control Practices Advisory Committee Guideline for Prevention of Surgical Site Infection.*
AJIC 1999;27:97-134.

Much Cleaner Cuts

PROBLEM: Infection related to surgery  
PROPOSAL: Better use of antibiotics, don’t shave with razor prior to surgery, tighten control of blood sugar  
POSSIBLE LIVES SAVED: 8,000

A hospital is a risky place for people who have had surgery. No matter how much antibacterial solution is painted on before the first cut, opening the body invites lurking microbes. Infections at the surgery site complicate an estimated 780,000 operations a year, or more than 1 in every 40 procedures. For abdominal surgery, the likelihood is as high as 1 in 5. And the complications are tough to treat. Infected patients are two to three times more likely to die and are hospitalized an average of seven days longer than uninfected patients who had the same operation.

Even before the 100K campaign got underway, IHI had been working with a group of 56 hospitals on strategies to lower the rate of surgical-site infections. Results of the yearlong effort, published last month in the American Journal of Surgery, showed a re-
Pathophysiology of Shaving & SSI

• Hair removal with a razor can disrupt skin integrity
• Microscopic exudative rashes and skin abrasions can occur during hair removal.
• These rashes and skin abrasions can provide a portal of entry for microorganisms
### Preoperative Hair Removal: Summary of the Data

</tr>
<tr>
<td>Moro et al. <em>Ann Ital Chir LXXVII</em> 1,1996.13-19.</td>
<td>Prospective analysis of 2,262 clean surgeries in eight general wards and one thoracic ward. 3.7% developed SSI  Logistic regression analysis: 7 risk factors- advanced age, obesity, high risk procedures, OR duration&gt;2 hours, preoperative shaving, open surgical drains &gt; 3 days</td>
</tr>
</tbody>
</table>
Pre-op Hair Removal

• Conclusions from a review of 20 studies:
  – several randomized & observational studies with controls show that either wet or dry shaving the evening before the procedure results in a significantly higher infection rate than depilation or electric clipping
  – there are no convincing differences in the incidence of postoperative SSIs between electric clipping, depilation, or no hair removal
  – If hair removal is anticipated, removal with clippers should be performed as close as possible to the time of the procedure

Perioperative Normothermia
Physiologic Effects of Hypothermia

Anesthetic drugs, opioids, sedatives

↓

Impaired thermoregulatory control

Vasoconstriction

↓ Tissue oxygenation

↓ Production of superoxide radicals

↓ Collagen deposition

↓ Killing of pathogens by neutrophils

↑ Risk of SSI
Perioperative Normothermia

- Blinded, randomized trial of 421 patients undergoing clean surgery (breast, varicose vein or hernia) comparing routine preoperative care to systemic warming (forced air warming blanket 30 minutes preop) to local warming (30 minute preop warming of planned incision with a radiant dressing)

Perioperative Glycemic Control
Perioperative Glucose Control

- Poor glucose control has been shown to be an independent risk factor for SSI in multiple studies
- Risk is increased due to vascular disease, neutrophil dysfunction, impairment of complement & antibodies
- Intervention: maintain glucose at 151-200 mg/dL via a continuous insulin infusion
Perioperative Glucose Control

- 141 diabetic patients undergoing CABG were randomized to tight glycemic control (125-200 mg/dL) with GIK or standard therapy (<250 mg/dL) using SQ SSI beginning before anesthesia & continuing for 12 hours after surgery.

</table>
| • Meers et al. *Journal of Hygiene*. 1978  
  • Kikuchi et al. *Acta Derm Venereol*. 1999. | Surgical hand preparation requiring scrubbing with a **brush** damages the skin and leads to increased shedding of bacteria and squamous epithelial cells |
  • Bornside GH. *Surgery*, 1968. | Scrubbing with a disposable **sponge** or combination **sponge-brush** has reduced bacterial counts on the hands as effectively as scrubbing with a brush. |
  • Loeb et al. *Am J Infect Control*, 1997 | Neither brush nor sponge is necessary to reduce bacterial counts on the hands of surgical staff to acceptable levels |

---

CDC MMWR- Guideline For Hand Hygiene in Healthcare Setting, October 25, 2002
Comparison of Different Regimens for Surgical Hand Preparation

• Prospective clinical trial
  • To compare the microbiology and skin condition of hands when using a traditional surgical scrub (TSS) with a detergent-based antiseptic containing 4% chlorhexidine gluconate (CHG) vs. a short application without scrub of a waterless hand preparation (HP) containing 61% ethyl alcohol, 1% CHG, and emollients.

• Endpoints:
  • antimicrobial effectiveness
  • effect on skin condition
  • time required

**Additional costs for consideration**

- **Weight of water waste per use**
  - Empty 500 mL bottle
  - Nail cleaner
  - Used scrub brush and packaging
  - Subtotal weight of waste per use
  - Water (2 gallons per minute flow rate)
  - Reusable sterile towel

- **Additional waste**
  - 12 gallons
  - none

Larson et al found the HP protocol less expensive

---

*At time of study, the waterless product was under US Food and Drug Administration review and not for sale. The price is an estimate.

* Manufacturers’ directions for use for the chlorhexidine preloaded scrub brush require a total scrub time of six minutes.

* Application and dry time for the waterless product was observed to be approximately two minutes.

* Many institutions calculate the cost per minute for maintaining an active OR, including overhead and staff members. If available, this cost should be used.

* Figure provided is per use weight (ie. 125 g for empty bottle divided by 80 uses per bottle).
Comparison of Different Regimens for Surgical Hand Preparation

Larson et al. AORN Journal, February 2001
Comparison of Different Regimens for Surgical Hand Preparation

Conclusion:

• The HP was associated with less skin damage ($P = .002$) and lower microbial counts postscrub at days five ($P = .002$) and 19 ($P = .02$).

• The HP protocol had shorter contact time (HP mean [M] = 80.7 seconds; TSS M = 144.9 seconds; $P < .0001$), and more subjects preferred the HP regimen ($P = .001$).

• The HP performed better than the TSS, was less costly, and should be evaluated in larger trials and considered for widespread implementation.

Hand-Rubbing With an Aqueous Alcoholic Solution vs Traditional Surgical Hand-Scrubbing and 30-Day Surgical Site Infection Rates A Randomized Equivalence Study
Study Overview

• Objective: to compare the effectiveness of hand-cleansing protocols to prevent SSI
• Design: prospective, randomized equivalence trial with crossover
• Setting: six surgical services from teaching and non-teaching hospitals in France
• Patients: A total of 4387 consecutive patients who underwent clean and clean contaminated surgery between January 1-May 1, 2001.

Study Overview

• Interventions
  – 2 hand-cleansing methods used alternately every other month
    • 75% aqueous alcohol solution:
      – Hand-rubbing involved a 75% AAS containing propanol-1, propanol-2, and mecetronium etilsulfate
      – Prior to the first procedure of the day, or if the hands were visibly soiled, the surgical team was instructed to use a nonantiseptic soap for a 1-minute hand wash
      – The hands and forearms were rinsed with nonsterile tap water and wiped carefully with nonsterile paper. The user was instructed to take enough AAS to fully cover the hands and forearms (at least 5 mL, which represents at least 4 pump strokes), and to apply it twice for 2 minutes 30 seconds (for a total of 5 minutes) without drying.
    • Hand scrubbing protocol with antiseptic preparation containing 4% povidone iodine or 4% chlorhexidine gluconate

Data Analysis

• Primary endpoint- SSI at 30 days
  – Equivalence study

• Secondary endpoints- compliance and tolerance

*ASA indicates American Society of Anesthesiologists. The ASA physical status classification indicates class 1, a healthy patient; class 2, a patient with mild systemic disease; class 3, a patient with severe systemic disease; class 4, a patient with severe systemic disease that is a constant threat; and class 5, a moribund patient who is not expected to survive without an operation.

*Time required for the nonantiseptic hand wash prior to hand-rubbing with aqueous alcoholic solution has been excluded.

†‡ Greater compliance observed with hand rubbing alcohol

Study Conclusions

- Hand rubbing protocol with aqueous alcoholic solution was as effective as traditional hand scrubbing with antiseptic soap in preventing surgical site infections in a 30 day follow-up.
- Hand rubbing protocol with aqueous alcoholic solution was better tolerated by surgical teams and improved compliance with hygiene guidelines.
- Hand rubbing protocol with aqueous alcoholic solution can be safely used as an alternative to traditional surgical hand-scrubbing.

30%-40% of all Nosocomial Infections are Attributed to Cross Transmission:
The Importance of Hand Hygiene
The inanimate environment is a reservoir of pathogens

X represents a positive Enterococcus culture

The pathogens are ubiquitous

~ Contaminated surfaces increase cross-transmission ~

Majority of respondents reported excellent compliance with IC practices

Berhe M, Edmond MB, G Bearman in AJIC 33;1 February 2005, 55-57
Alcohol Based Hand Sanitizers

• CDC/SHEA hand antiseptic agents of choice
  – Recommended by CDC based on strong experimental, clinical, epidemiologic, and microbiologic data
  – Antimicrobial superiority
    • Greater microbicidal effect
    • Prolonged residual effect
  – Ease of use and application
Alcohol based hand hygiene solutions

Quick: 5-15 seconds

Easy to use

Very effective antisepsis due to bactericidal properties of alcohol
Conclusion

• Infection control is immediately relevant to surgical practice
• Research has led to well defined risk factors and risk reduction interventions for:
  – VAP, UTI, BSI, and SSI
• Sadly, implementation of risk reduction practices is frequently not uniform and poorly sustained
• Consumer advocacy groups, 3rd party payers, and regulatory agencies are increasingly mandating health system quality improvement through reporting of IC process of care measures
The Importance of Infection Control in Limiting the Cross Transmission of Pathogens

Supplemental Perioperative Oxygen

- Surgical wounds disrupt the local vascular supply as a result of injury & thrombosis of vessels, which cause wounds to be hypoxic as compared to normal tissue (often <30 mmHg)
- Increasing the PaO2 increases bactericidal superoxide radicals, but also cause endothelial cell damage, tissue necrosis, & impair the antibacterial function of macrophages
### Supplemental Perioperative Oxygen

- 500 patients undergoing elective colorectal resection randomized to 30% O\textsubscript{2} vs. 80% O\textsubscript{2} during surgery & first 2 hours of recovery
